The Impact of Early Experiences on Brain and Behavioral Development

Nathan Fox, Ph.D.
Distinguished University Professor, University of Maryland
Member, National Scientific Council on the Developing Child

Wisconsin Family Impact Seminar
March 19, 2019
Three Core Concepts of Development

1. Brain Architecture is Established Early in Life and Supports Lifelong Learning, Behavior, and Health

2. Stable, Caring Relationships and “Serve and Return” Interaction Shape Brain Architecture

3. Toxic Stress in the Early Years of Life Can Derail Healthy Development
Experiences Build Brain Architecture

NATIONAL SCIENTIFIC COUNCIL ON THE DEVELOPING CHILD
Brains are built over time, starting in the earliest years of life. Simple skills come first; more complex skills build on top of them.

Cognitive, emotional, and social capabilities are inextricably intertwined throughout the life course.

A strong foundation in the early years improves the odds for positive outcomes, and a weak foundation increases the odds of later difficulties.
The Ability to Change Brains Decreases Over Time

Normal Brain Plasticity Influenced by Experience

Physiological “Effort” Required to Enhance Neural Connections

Age (Years)
Neural Circuits are Wired in a Bottom-Up Sequence

- Sensory Pathways (Vision, Hearing)
- Language
- Higher Cognitive Function

Birth (Months) (Years)

Experiences Shape Brain Architecture by Over-Production Followed by Pruning

700 synapses are formed per second in the early years.
Sensitive Periods

- Are limited time periods during which the effect of experience on the brain is particularly strong
- Allow experience to instruct neural circuits to process information in an adaptive way
- Provide information that is essential for normal development and may permanently alter performance
Early Windows of Experience Shape Brain Function

Monocular deprivation in early infancy led to deficits in brain organization in visual cortex.
Studies of Infants Born with Bilateral Cataracts—Timing of Surgical Removal

**FIGURE 9** Examples of sensitive periods across four aspects of vision. Gray bars represent periods of normal development, and black bars represent sensitive periods for damage. Ages indicating the end of each period are approximate and apply to the conditions described in the text. For convenience, we chose birth as the beginning of each sensitive period for damage, although the actual ages are unknown. The graph illustrates that the period of normal development ends at ages varying from a few months (asymmetry of OKN for large, high-contrast patterns) to 6 or 7 years of age (letter acuity, global motion, and perhaps light sensitivity in the mid-periphery—for which 7 years is the youngest age tested beyond infancy). The sensitive period for damage can be considerably longer or shorter than the period of normal development.
Before 9-10 months of age, infants can discriminate the sounds of all languages. By the end of the first year of life, they are able to discriminate only the language(s) they hear in their environment.

Interaction Shapes Brain Circuitry
Serve & Return Builds Brains and Skills

Young children naturally reach out for interaction through babbling, facial expressions, and gestures, and adults respond in kind.

These “serve and return" interactions are essential for the development of healthy brain circuits.

Therefore, systems that support the quality of relationships in early care settings, communities, and homes also support the development of sturdy brain architecture.
Barriers to Educational Achievement Emerge at a Very Young Age

Cumulative Vocabulary (Words)

- College Educated Parents
- Working Class Parents
- Low SES Parents

Child’s Age (Months)

An “Air Traffic Control System” in the Brain

Executive functioning is a group of skills that help us focus on multiple streams of information at the same time, set goals and make plans, make decisions in light of available information, revise plans, and resist hasty actions.

➢ a key biological foundation of school readiness, as well as outcomes in health and employability
What are Executive Function Skills?

**Inhibitory Control** — filter thoughts and impulses to resist temptations and distractions

**Working Memory** — hold and manipulate information in our heads over short periods of time

**Cognitive Flexibility** — adjust to changed demands, priorities, or perspectives
Higher Childhood Self-Control Predicts Better Adult Health

Toxic Stress Derails Healthy Development

NATIONAL SCIENTIFIC COUNCIL ON THE DEVELOPING CHILD
Toxic Prolonged activation of stress response systems in the absence of protective relationships.

The Biology of Adversity: Three Levels of Stress

Positive
Brief increases in heart rate, mild elevations in stress hormone levels.

Tolerable
Serious, temporary stress responses, buffered by supportive relationships.

Toxic
Prolonged activation of stress response systems in the absence of protective relationships.
Learning how to cope with moderate, short-lived stress can build a healthy stress response system.

Toxic stress—when the body’s stress response system is activated excessively—can weaken developing brain architecture.

Without caring adults to buffer children, toxic stress associated with extreme poverty, neglect, abuse, or severe maternal depression can have long-term consequences for learning, behavior, and both physical and mental health.
Persistent Stress Changes Brain Architecture

Normal

Prefrontal Cortex and Hippocampus

Chronic stress

Typical - neuron with many connections

Neuron damaged by toxic stress – fewer connections

Bock et al. (2005)
In 1995-1997, Kaiser Permanente in California conducted a survey of adult patients in which they were asked to identify a range of adverse childhood experiences (abuse, neglect, household challenges).

Researchers later found that the cumulative number of these experiences in childhood was related to adult health and disease.

Neglect is the Most Prevalent Form of Child Maltreatment

Each state defines the types of child abuse and neglect in its own statute and policy, guided by federal standards, and establishes the level of evidence needed to substantiate a report of maltreatment. The data above, from the National Child Abuse and Neglect Data System (NCANDS), reflects the total number of victims (defined as a child for whom the state determined at least one report of maltreatment was found to be substantiated or indicated) as reported by all 50 states, the District of Columbia, and Puerto Rico, between Oct. 1, 2009, and Sept. 30, 2010. “Other” includes abandonment, threats of harm, and drug addiction.

Effects of Profound Neglect on Brain Development

Why neglect is bad for the brain

• Brain expects input it doesn’t receive, so its wiring is altered

• Particularly egregious if experiences expected to occur during a sensitive period fail to occur (e.g., patterned light, sound, caregiving)
Extreme Neglect Reduces Brain Power

Positive Relationships  Extreme Neglect

There Are No Magic Bullets

Positive relationships and quality learning experiences can be promoted both at home and through a range of evidence-based parent education, family support, early care and education, and intervention services.

A balanced approach to emotional, social, cognitive, and language development will best prepare children for success in school and later in the workplace.
Effectiveness Factors for Early Care and Education Programs for Children From Birth to Age 5

- Qualified and well-compensated personnel
- Small group sizes and high adult-child ratios
- Language-rich environment
- Developmentally appropriate “curriculum”
- Safe physical setting
- Warm and responsive adult-child interactions
Science Points Toward a Two-Tiered Approach to Reducing Disparities

Basic health services and good quality early care and education can promote healthy development and early detection of problems in all children.

Targeted services for children experiencing tolerable or toxic stress can reduce disruptions of the developing nervous and immune systems that lead to later problems in learning, behavior, and health.
Significant brain development occurs in the first years of life.

Healthy brain and behavioral development require positive, sensitive, and responsive caregiving.

Toxic stress can derail healthy brain and behavioral development.

Providing support to families, good compensation to early childhood teachers, and good quality and basic health care services can go a long way toward enhancing positive outcomes.
